Synchronous Buck PWM and Linear Controller

Features

- **Provided Two Regulated Voltages**
  - **Synchronous Buck Converter**
  - **Linear Regulator**
- **Single 12V Power Supply Required**
- **Excellent Both Output Voltage Regulation**
  - **0.8V Internal Reference**
  - **±1% Over Line Voltage and Temperature**
- **Integrated Soft-Start for PWM and Linear Outputs**
- **Programmable Frequency Range from 150kHz to 1000kHz**
- **Voltage Mode PWM Control Design and Up to 89% (Typ.) Duty Cycle**
- **Under-Voltage Protection for PWM and Linear Output**
- **Over-Current Protection for PWM Output**
  - **Sense Low-Side MOSFET's $R_{DS(ON)}$**
- **SOP-14, QSOP-16 and QFN4x4-16 packages**
- **Lead Free and Green Devices Available (RoHS Compliant)**

General Description

The APW7067N integrates synchronous buck PWM and linear controller, as well as monitoring and protection functions into a single package. The synchronous PWM controller drives dual N-channel MOSFETs, which provides one controlled power output with under-voltage and over-current protections. Linear controller drives an external N-channel MOSFET with under-voltage protection.

The APW7067N provides excellent regulation for output load variation. An internal 0.8V temperature-compensated reference voltage is designed to meet the requirement of low output voltage applications. The switching frequency is adjustable from 150kHz to 1000kHz.

The APW7067N with excellent protection functions: POR, OCP and UVP. The Power-On-Reset (POR) circuit can monitor VCC12 supply voltage exceeds its threshold voltage while the controller is running, and a built-in digital soft-start provides both outputs with controlled rising voltage. The Over-Current Protection (OCP) monitors the output current by using the voltage drop across the lower MOSFET's $R_{DS(ON)}$, comparing with internal V_{OCP} (0.25V), eliminating the need for a current sensing resister. When the output current reaches the trip point, the controller will shutdown the IC directly, and latch the converter's output. The Under-Voltage Protection (UVP) monitors the voltages of FB and FBL pins for short-circuit protection. When the V_{FB} or V_{FBL} is less than 50% of V_{REF}, the controller will shutdown the IC directly.

Note: ANPEC lead-free products contain molding compounds/die attach materials and 100% matte tin plate termination finish; which are fully compliant with RoHS. ANPEC lead-free products meet or exceed the lead-free requirements of IPC/JEDEC J-STD-020C for MSL classification at lead-free peak reflow temperature. ANPEC defines "Green" to mean lead-free (RoHS compliant) and halogen free (Br or Cl does not exceed 900ppm by weight in homogeneous material and total of Br and Cl does not exceed 1500ppm by weight).

Function Pin Description

VCC12

Power supply input pin. Connect a nominal 12V power supply to this pin. The power-on reset function monitors the input voltage at this pin. It is recommended that a decoupling capacitor (1 to 10μF) be connected to GND for noise decoupling.

BOOT

This pin provides the bootstrap voltage to the upper gate driver for driving the N-channel MOSFET. An external capacitor from PHASE to BOOT, an internal diode, and the power supply valtage V_{CC12}, generates the bootstrap voltage for the upper gate diver (UGATE).

PHASE

This pin is the return path for the upper gate driver. Connect this pin to the upper MOSFET source, and connect a capacitor to BOOT for the bootstrap voltage. This pin is also used to monitor the voltage drop across the lower MOSFET for over-current protection.

GND

This pin is the signal ground pin. Connect the GND pin to a good ground plane.

PGND

This pin is the power ground pin for the lower gate driver. It should be tied to GND pin on the board.

COMP

This pin is the output of PWM error amplifier. It is used to set the compensation components.

FB

This pin is the inverting input of the PWM error amplifier. It is used to set the output voltage and the compensation components. This pin is also monitored for under-voltage protection, when the FB voltage is under 50% of reference voltage (0.4V), both outputs will be shut

- downed immediately.

UGATE

This pin is the gate driver for the upper MOSFET of PWM output.

LGATE

This pin is the gate driver for the lower MOSFET of PWM output.

DRIVE

This pin drives the gate of an external N-channel MOSFET for linear regulator. It is also used to set the compensation for some specific applications, for example, with low values of output capacitance and ESR.

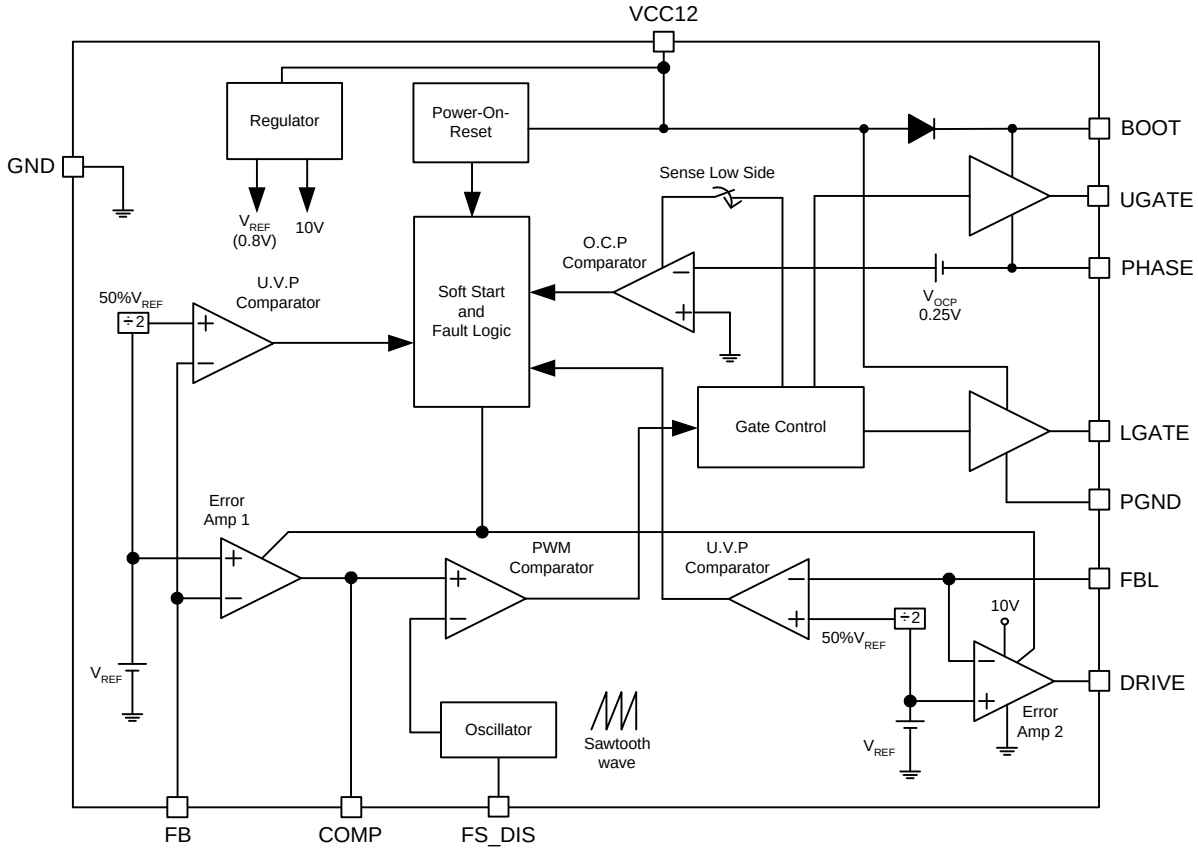
FBL

This pin is the inverting input of the linear regulator error amplifier. It is used to set the output voltage. This pin is also monitored for under-voltage protection, when the FBL voltage is under 50% of reference voltage (0.4V), both outputs will be shutdown immediately.

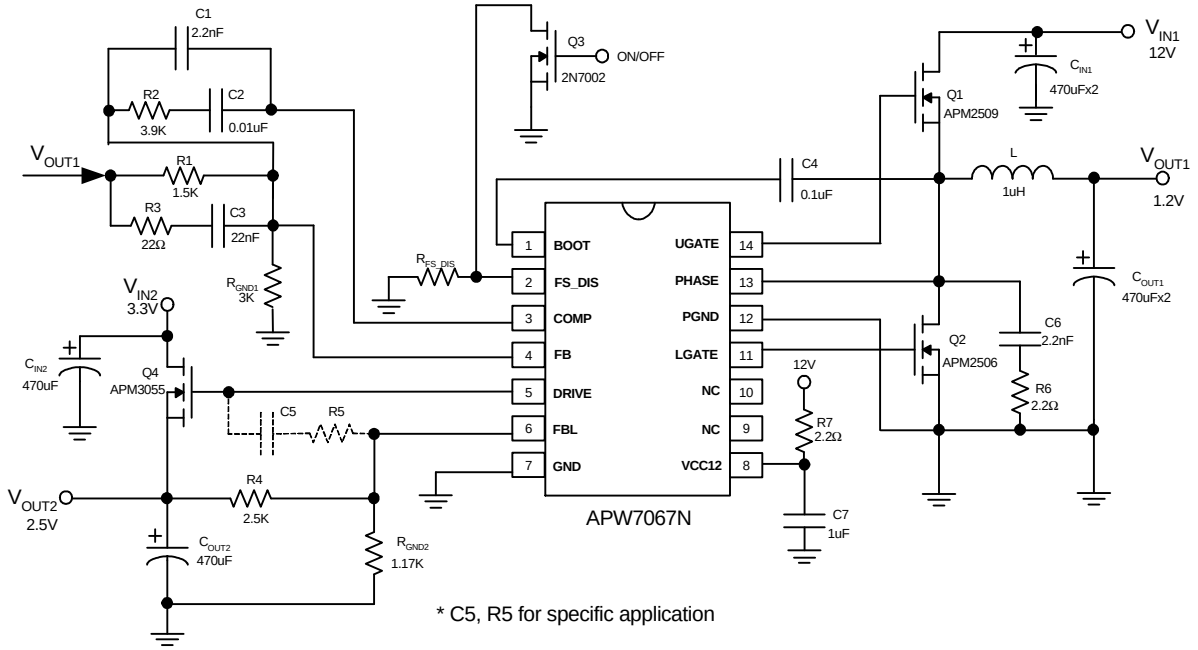
FS_DIS

This pin be allowed to adjust the switching frequency. Connect a resistor from FS_DIS pin to the ground to increase the switching frequency. This pin also provides shutdown function, use an open drain logic signal to pull this pin low to disable both outputs, leave open to enable both outputs.

Block Diagram



Typical Application Circuits



Function Description

Power-On-Reset (POR)

The Power-On-Reset (POR) function of APW7067N continually monitors the input supply voltage (V_{CC12}), ensures the supply voltage exceed its rising POR threshold voltage. The POR function initiates soft-start interval operation while VCC12 voltage exceeds its POR threshold and inhibits operation under disabled status.

Soft-Start

Figure 1. shows the soft-start interval. When V_{CC12} reaches the rising POR threshold voltage, the internal reference voltage is controlled to follow a voltage proportional to the soft-start voltage. The soft-start interval is variable by the oscillator frequency. The formulation is given by:

$$T_{SS} = \Delta(t_2 - t_1) = \frac{1}{F_{OSC}} \times 1280$$

Figure 2. shows more detail of the FB and FBL voltage ramps. The FB and FBL voltage soft-start ramps are formed with many small steps of voltage. The voltage of one step is about 20mV in V_{FB} and V_{FBL}, and the period of one step is about 32/FOSC. This method provides a controlled voltage rise and prevents the large peak current to charge the output capacitors. The FB voltage compares the FBL voltage to shift to an earlier time the establishment as Figure2. The voltage establishment time difference for V_{FB} and V_{FBL} is variable by the oscillator. The formulation is given by:

$$\Delta(t_4 - t_3) = \frac{1}{F_{OSC}} \times 320 = \frac{1}{4} \times T_{SS}$$

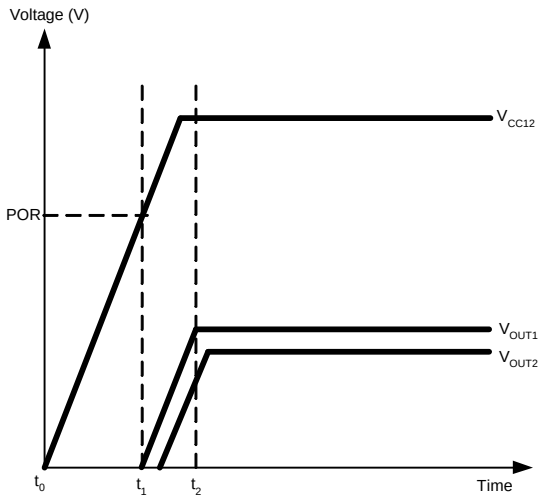


Figure 1. Soft-Start Interval

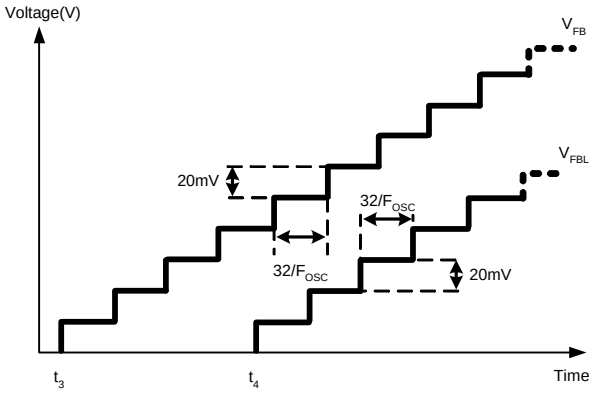

Figure 2. The Controlled Stepped FB and FBL Voltage during Soft-Start

Over-Current Protection

The over-current protection monitors the output current by using the voltage drop across the lower MOSFET's $R_{DS(ON)}$ and this voltage drop will be compared with the internal 0.25V reference voltage. When the voltage drop across the lower MOSFET's $R_{DS(ON)}$ is larger than 0.25V, an over-current condition is detected, the controller will shutdown the IC directly, and latch the converter's output.

The threshold of the over current limit is given by:

$$I_{LIMIT} = \frac{V_{OCP}(0.25V)}{R_{DS(ON)}(Low\_Side)}$$

For the over-current is never occurred in the normal operating load range; the variation of all parameters in the above equation should be determined.

- The MOSFET's $R_{DS(ON)}$ is varied by temperature and gate to source voltage, the user should determine the maximum $R_{DS(ON)}$ in manufacture's datasheet.
- The minimum V_{OCP} should be used in the above equation.
- Note that the I_{LIMIT} is the current flow through the lower MOSFET; I_{LIMIT} must be greater than maximum output current add the half of inductor ripple current.

Under Voltage Protection

The FB and FBL pin are monitored during converter operation by their own Under Voltage (UV) comparator. If the FB or FBL voltage drop below 50% of the reference voltage (50% of 0.8V = 0.4V), a fault signal is internally generated, and the device turns off both high-side

Function Description (Cont.)

Under Voltage Protection (Cont.)

and low-side MOSFET and the converter's output is latched to be floating.

Shutdown and Enable

Pulling the FS_DIS voltage to GND by an open drain transistor, shown in typical application circuit, shutdown the APW7067N PWM controller. In shutdown mode, the UGATE and LGATE turn off and pull to PHASE and GND respectively.

Switching Frequency

The APW7067N provides the adjustable oscillator switching frequency . The switching frequency is determined by the value of R_{FS_DIS} (from FS_DIS pin to GND), the adjustable range from150kHz to 1000kHz .

Figure 3. shows how to select the resistor for the desired frequency. If the IC is operated in higher frequencies (ex. 600 kHz or above), the slope of the curve is steep, and a small change in resistance will have a big effect on the frequency. At lower frequencies, the slope of the curve is much less steep, even a large change in resistor value doesn't change the frequency too much. Figure 4. shows more detail for the higher frequency and Figure5. shows the lower frequency.

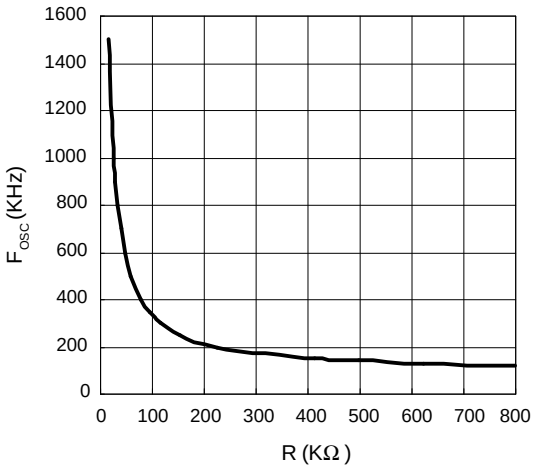

Figure 3. Oscillator Frequency vs. R_{FS-DIS}

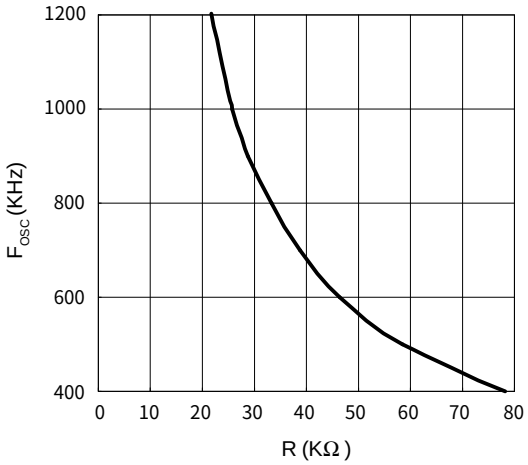

Figure 4. Oscillator Frequency vs.R_{FS-DIS} (High Frequency)

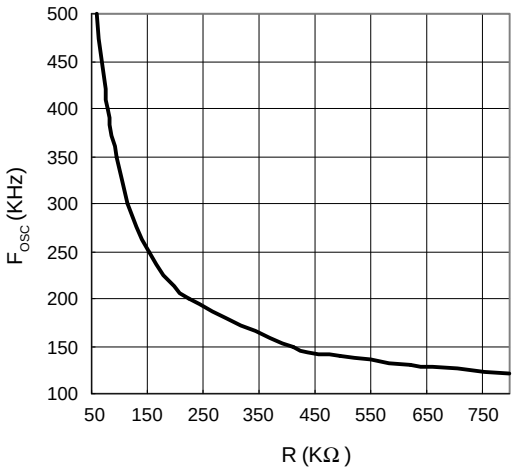

Figure 5. Oscillator Frequency vs.R_{FS-DIS} (Low Frequency)

Application Information

Output Voltage Selection

The output voltage of PWM converter can be programmed with a resistive divider. Use 1% or better resistors for the resistive divider is recommended. The FB pin is the inverter input of the error amplifier, and the reference voltage is 0.8V. The output voltage is determined by:

$$V_{OUT1} = 0.8 \times \left(1 + \frac{R1}{R_{GND1}}\right)$$

Where R1 is the resistor connected from V_{OUT1} to FB and R_{GND1} is the resistor connected from FB to GND.

The linear regulator output voltage V_{OUT2} is also set by means of an external resistor divider. The FBL pin is the inverter input of the error amplifier, and the reference voltage is 0.8V. The output voltage is determined by:

$$V_{OUT2} = 0.8 \times \left(1 + \frac{R4}{R_{GND2}}\right)$$

Where R4 is the resistor connected from V_{OUT2} to FBL and R_{GND2} is the resistor connected from FBL to GND.

Linear Regulator Input/Output Capacitor Selection

The input capacitor is chosen based on its voltage rating. Under load transient condition, the input capacitor will momentarily supply the required transient current. The output capacitor for the linear regulator is chosen to minimize any droop during load transient condition. In addition, the capacitor is chosen based on its voltage rating.

Linear Regulator Input/Output MOSFET Selection

The maximum DRIVE voltage is about 10V when V_{CC12} is equal 12V. Since this pin drives an external N-channel MOSFET, therefore the maximum output voltage of the linear regulator is dependent upon the V_{GS}.

$$V_{OUT2MAX} = 10 - V_{GS}$$

Another criterion is its efficiency of heat removal. The power dissipated by the MOSFET is given by:

$$P_D = I_{OUT2} \times (V_{IN2} - V_{OUT2})$$

Where I_{OUT2} is the maximum load current, V_{OUT2} is the nominal output voltage.

In some applications, heatsink might be required to help maintain the junction temperature of the MOSFET below its maximum rating.

Linear Regulator Compensation Selection

The linear regulator is stable over all loads current. However, the transient response can be further enhanced by connecting a RC network between the FBL and DRIVE pin. Depending on the output capacitance and load current of the application, the value of this RC network is then varied.

PWM Compensation

The output LC filter of a step down converter introduces a double pole, which contributes with -40dB/decade gain slope and 180 degrees phase shift in the control loop. A compensation network among COMP, FB and V_{OUT1} should be added. The compensation network is shown in Fig. 9. The output LC filter consists of the output inductor and output capacitors. The transfer function of the LC filter is given by:

$$GAIN_{LC} = \frac{1 + s \times ESR \times C_{OUT1}}{s^2 \times L \times C_{OUT1} + s \times ESR \times C_{OUT1} + 1}$$

The poles and zero of this transfer functions are:

$$F_{LC} = \frac{1}{2 \times \pi \times \sqrt{L \times C_{OUT1}}}$$

$$F_{ESR} = \frac{1}{2 \times \pi \times ESR \times C_{OUT1}}$$

The F_{LC} is the double poles of the LC filter, and F_{ESR} is the zero introduced by the ESR of the output capacitor.

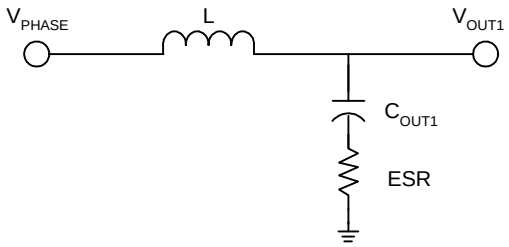

Figure 6. The Output LC Filter

Application Information (Cont.)

PWM Compensation (Cont.)

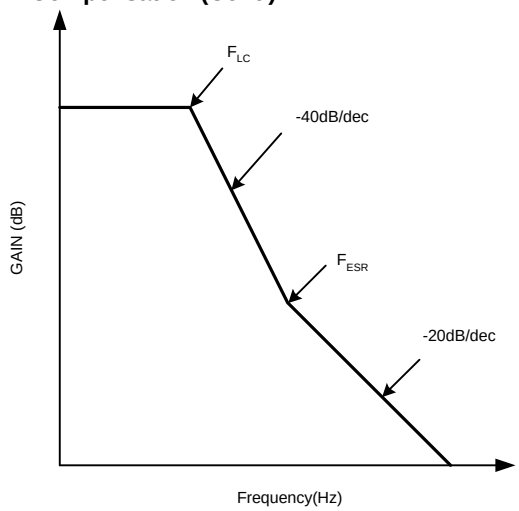

Figure 7. The LC Filter GAIN and Frequency

The PWM modulator is shown in Figure 8. The input is the output of the error amplifier and the output is the PHASE node. The transfer function of the PWM modulator is given by:

$$GAIN_{PWM} = \frac{V_{IN}}{\Delta V_{OSC}}$$

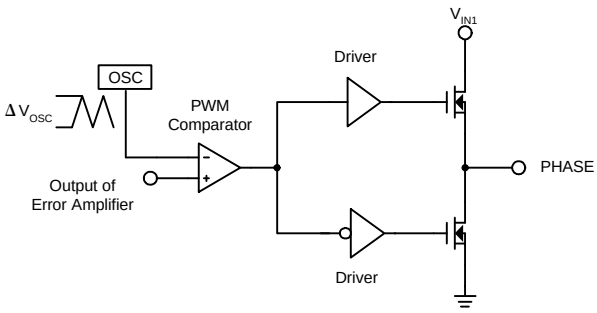

Figure 8. The PWM Modulator

The compensation network is shown in Figure 9. It provides a close loop transfer function with the highest zero crossover frequency and sufficient phase margin.

The transfer function of error amplifier is given by:

$$GAIN_{AMP} = \frac{V_{COMP}}{V_{OUT1}} = \frac{\frac{1}{sC1} // \left(R2 + \frac{1}{sC2}\right)}{R1 // \left(R3 + \frac{1}{sC3}\right)}$$

$$= \frac{R1+R3}{R1 \times R3 \times C1} \times \frac{\left(s + \frac{1}{R2 \times C2}\right) \times \left(s + \frac{1}{(R1+R3) \times C3}\right)}{s\left(s + \frac{C1+C2}{R2 \times C1 \times C2}\right) \times \left(s + \frac{1}{R3 \times C3}\right)}$$

The poles and zeros of the transfer function are:

$$F_{Z1} = \frac{1}{2 \times \pi \times R2 \times C2}$$

$$F_{Z2} = \frac{1}{2 \times \pi \times (R1+R3) \times C3}$$

$$F_{P1} = \frac{1}{2 \times \pi \times R2 \times \left(\frac{C1 \times C2}{C1+C2}\right)}$$

$$F_{P2} = \frac{1}{2 \times \pi \times R3 \times C3}$$

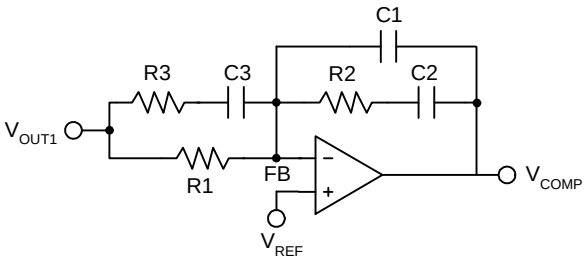

Figure 9. Compensation Network

The closed loop gain of the converter can be written as:

$$GAIN_{LC} \, X \, GAIN_{PWM} \, X \, GAIN_{AMP}$$

Figure 10. shows the asymptotic plot of the closed loop converter gain, and the following guidelines will help to design the compensation network. Using the below guidelines should give a compensation similar to the curve plotted. A stable closed loop has a -20dB/ decade slope and a phase margin greater than 45 degree.

1. Choose a value for R1, usually between 1K and 5K.

2. Select the desired zero crossover frequency

F_O: (1/5 ~ 1/10) X F_S >F_O>F_{ESR}

Use the following equation to calculate R2:

$$R2 = \frac{\Delta V_{OSC}}{V_{IN}} \times \frac{F_O}{F_{LC}} \times R1$$

3. Place the first zero F_{Z1} before the output LC filter double pole frequency F_{LC}.

F_{Z1} = 0.75 X F_{LC}

Calculate the C2 by the equation:

$$C2 = \frac{1}{2 \times \pi \times R2 \times F_{LC} \times 0.75}$$

4. Set the pole at the ESR zero frequency F_{ESR}:

F_{P1} = F_{ESR}

Calculate the C1 by the equation:

$$C1 = \frac{C2}{2 \times \pi \times R2 \times C2 \times F_{ESR} - 1}$$

Application Information (Cont.)

PWM Compensation (Cont.)

5. Set the second pole F_{P2} at the half of the switching frequency and also set the second zero F_{Z2} at the output LC filter double pole F_{LC}. The compensation gain should not exceed the error amplifier open loop gain, check the compensation gain at F_{P2} with the capabilities of the error amplifier.

$$F_{P2} = 0.5 \times F_S$$

$$F_{Z2} = F_{LC}$$

Combine the two equations will get the following component calculations:

$$R3 = \frac{R1}{\frac{F_S}{2 \times F_{LC}} - 1}$$

$$C3 = \frac{1}{\pi \times R3 \times F_S}$$

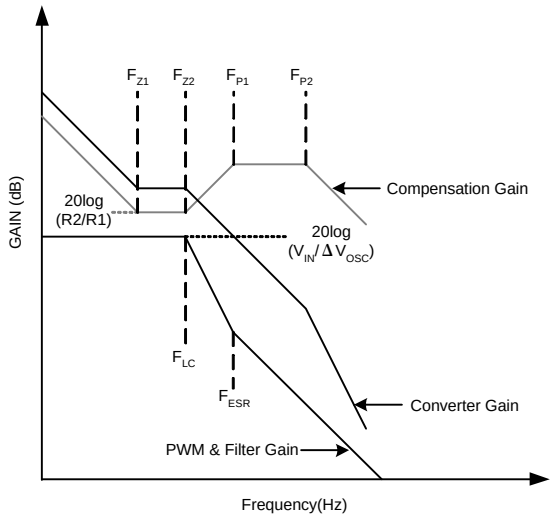

Figure 10. Converter Gain and Frequency

Output Inductor Selection

The inductor value determines the inductor ripple current and affects the load transient response. Higher inductor value reduces the inductor's ripple current and induces lower output ripple voltage. The ripple current and ripple voltage can be approximated by:

$$I_{RIPPLE} = \frac{V_{IN1} - V_{OUT1}}{F_S \times L} \times \frac{V_{OUT1}}{V_{IN1}}$$

$$\Delta V_{OUT1} = I_{RIPPLE} \times ESR$$

where Fs is the switching frequency of the regulator.

Although increase of the inductor value and frequency reduces the ripple current and voltage, a tradeoff will exist between the inductor's ripple current and the regulator load transient response time.

A smaller inductor will give the regulator a faster load transient response at the expense of higher ripple current. Increasing the switching frequency (F_S) also reduces the ripple current and voltage, but it will increase the switching loss of the MOSFET and the power dissipation of the converter. The maximum ripple current occurs at the maximum input voltage. A good starting point is to choose the ripple current to be approximately 30% of the maximum output current. Once the inductance value has been chosen, select an inductor that is capable of carrying the required peak current without going into saturation. In some types of inductors, especially core that is made of ferrite, the ripple current will increase abruptly when it saturates. This will result in a larger output ripple voltage.

Output Capacitor Selection

Higher capacitor value and lower ESR reduce the output ripple and the load transient drop. Therefore, selecting high performance low ESR capacitors is intended for switching regulator applications. In some applications, multiple capacitors have to be parallel to achieve the desired ESR value. A small decoupling capacitor in parallel for bypassing the noise is also recommended, and the voltage rating of the output capacitors also must be considered. If tantalum capacitors are used, make sure they are surge tested by the manufactures. If in doubt, consult the capacitors manufacturer.

Input Capacitor Selection

The input capacitor is chosen based on the voltage rating and the RMS current rating. For reliable operation, select the capacitor voltage rating to be at least 1.3 times higher than the maximum input voltage. The maximum RMS current rating requirement is approximately $I_{OUT1}/2$, where I_{OUT1} is the load current. During power up, the input capacitors have to handle large amount of surge current. If tantalum capacitors are used, make sure they are surge

Application Information (Cont.)

Input Capacitor Selection (Cont.)

tested by the manufactures. If in doubt, consult the capacitors manufacturer. For high frequency decoupling, a ceramic capacitor 1μF can be connected between the drain of upper MOSFET and the source of lower MOSFET.

MOSFET Selection

The selection of the N-channel power MOSFETs are determined by the $R_{DS(ON)}$, reverse transfer capacitance (C_{RSS}) and maximum output current requirement. There are two components of loss in the MOSFETs: conduction loss and transition loss. For the upper and lower MOSFET, the losses are approximately given by the following:

$$P_{UPPER} = I_{OUT1}^{2}(1+ TC)(R_{DS(ON)})D + (0.5)(I_{OUT1})(V_{IN1})(t_{SW})F_S$$

$$P_{LOWER} = I_{OUT1}^{2}(1+ TC)(R_{DS(ON)})(1-D)$$

Where I_{OUT1} is the load current

TC is the temperature dependency of $R_{DS(ON)}$
F_S is the switching frequency
t_{SW} is the switching interval
D is the duty cycle

Note that both MOSFETs have conduction loss while the upper MOSFET include an additional transition loss. The switching internal, t_{SW}, is a function of the reverse transfer capacitance C_{RSS}. The (1+TC) term is to factor in the temperature dependency of the $R_{DS(ON)}$ and can be extracted from the "$R_{DS(ON)}$ vs Temperature" curve of the power MOSFET.

Layout Consideration

In any high switching frequency converter, a correct layout is important to ensure proper operation of the regulator. With power devices switching at 300KHz or above, the resulting current transient will cause voltage spike across the interconnecting impedance and parasitic circuit elements. As an example, consider the turn-off transition of the PWM MOSFET. Before turn-off, the MOSFET is carrying the full load current. During turn-off, current stops flowing in the MOSFET and is free-wheeling by the lower MOSFET and parasitic diode. Any parasitic inductance of the circuit generates a large voltage spike during the switching interval. In general, using short, wide printed circuit traces should minimize interconnecting impedances and the magnitude of voltage spike. And signal and power grounds are to be kept separate till combined using ground plane construction or single point grounding. Figure 11. illustrates the layout, with bold lines indicating high current paths; these traces must be short and wide. Components along the bold lines should be placed lose together. Below is a checklist for your layout:

- The metal plate of the bottom of the packages (QFN-16) must be soldered to the PCB and connected to the GND plane on the backside through several thermal vias.

- Keep the switching nodes (UGATE, LGATE and PHASE) away from sensitive small signal nodes since these nodes are fast moving signals. Therefore, keep traces to these nodes as short as possible.

- The traces from the gate drivers to the MOSFETs (UG, LG, DRIVE) should be short and wide.

- Place the source of the high-side MOSFET and the drain of the low-side MOSFET as close as possible. Minimizing the impedance with wide layout plane between the two pads reduces the voltage bounce of the node.

- Decoupling capacitor, compensation component, the resistor dividers and boot capacitors should be close their pins. (For example, place the decoupling ceramic capacitor near the drain of the high-side MOSFET as close as possible. The bulk capacitors are also placed near the drain).

- The input capacitor should be near the drain of the upper MOSFET; the output capacitor should be near the loads. The input capacitor GND should be close to the output capacitor GND and the lower MOSFET GND.

- The drain of the MOSFETs (V_{IN1} and PHASE nodes) should be a large plane for heat sinking.
